Implementing ITIL-Aligned Incident Management in Salesforce

Industry: Cybersecurity

Solution: Custom Incident Management Framework in Salesforce

Challenge

The organisation lacked a centralised, structured process to manage incidents, problems, and change requests. Without a formal incident management framework, tracking the lifecycle of technical issues was inconsistent, and cross-functional coordination between Security Operations Center (SOC) and Change Management teams was inefficient. There was also no standardised way to approve or escalate issues, leading to delayed resolutions and accountability gaps.

Objectives

The objective was to design and implement a robust Incident Management process within Salesforce that aligned with ITIL best practices. The solution needed to support the full lifecycle of incidents, from initial reporting to resolution, and incorporate related processes such as problem management and change management. It was also essential to ensure traceability, enforce approval workflows, and improve operational visibility.

Solutions

We implemented a customised ITIL-aligned Incident Management system in Salesforce using three key custom objects: Incidents, Problem Tickets, and Change Requests. A junction object and Flows were used to handle complex relationships and automate related record creation. Approval processes were added—Problem Tickets routed to the SOC Manager and Change Requests to the Change Manager—ensuring accountability, proper oversight, and reduced operational risk.

Results

- Centralised incident tracking across departments, improving transparency and coordination
- Standardised workflows aligned with ITIL best practices
- Automated relationship mapping between incidents, problems, and changes
- Faster resolution and escalation through defined approval processes
- Improved governance and auditability of operational issues and system changes
